

CS 6530 Applied Cryptography

July-Nov 2025

Introduction to Cryptography and Data Security

11th August 2025 – Session 2

Dr. Manikantan Srinivasan

(Material covered is based on Chapter 2 of
[Understanding Cryptography – Second Edition,](#)
[Serious Cryptography – Second Edition](#))

Modern Block Ciphers

- ◆ will now look at modern block ciphers
- ◆ one of the most widely used types of cryptographic algorithms
- ◆ provide secrecy and/or authentication services
- ◆ in particular will introduce DES (Data Encryption Standard)

Block vs Stream Ciphers

- ◆ block ciphers process messages in into blocks, each of which is then en/decrypted
- ◆ like a substitution on very big characters
 - 64-bits or more
- ◆ stream ciphers process messages a bit or byte at a time when en/decrypting
- ◆ many current ciphers are block ciphers
- ◆ hence are focus of course

Block Cipher Principles

- ◆ most symmetric block ciphers are based on a **Feistel Cipher Structure**
- ◆ needed since must be able to **decrypt** ciphertext to recover messages efficiently
- ◆ block ciphers look like an extremely large substitution
- ◆ would need table of 2^{64} entries for a 64-bit block
- ◆ instead create from smaller building blocks
- ◆ using idea of a product cipher

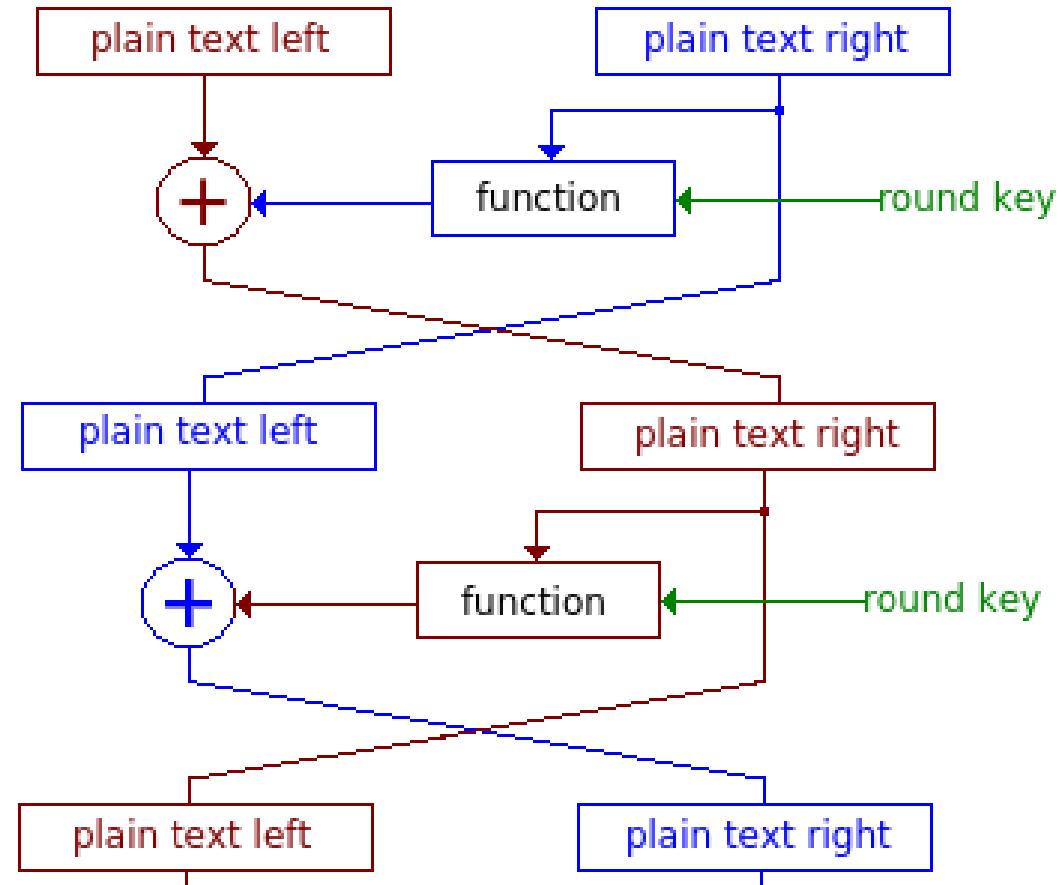

Confusion and Diffusion

- ◆ cipher needs to completely obscure statistical properties of original message
- ◆ a one-time pad does this
- ◆ more practically Shannon suggested combining elements to obtain:
- ◆ **confusion** – makes relationship between ciphertext and key as complex as possible
- ◆ **diffusion** – dissipates statistical structure of plaintext over bulk of ciphertext
- ◆ *Confusion means that the input (plaintext and encryption key) undergoes complex transformations, and diffusion means that these transformations depend equally on all bits of the input.*

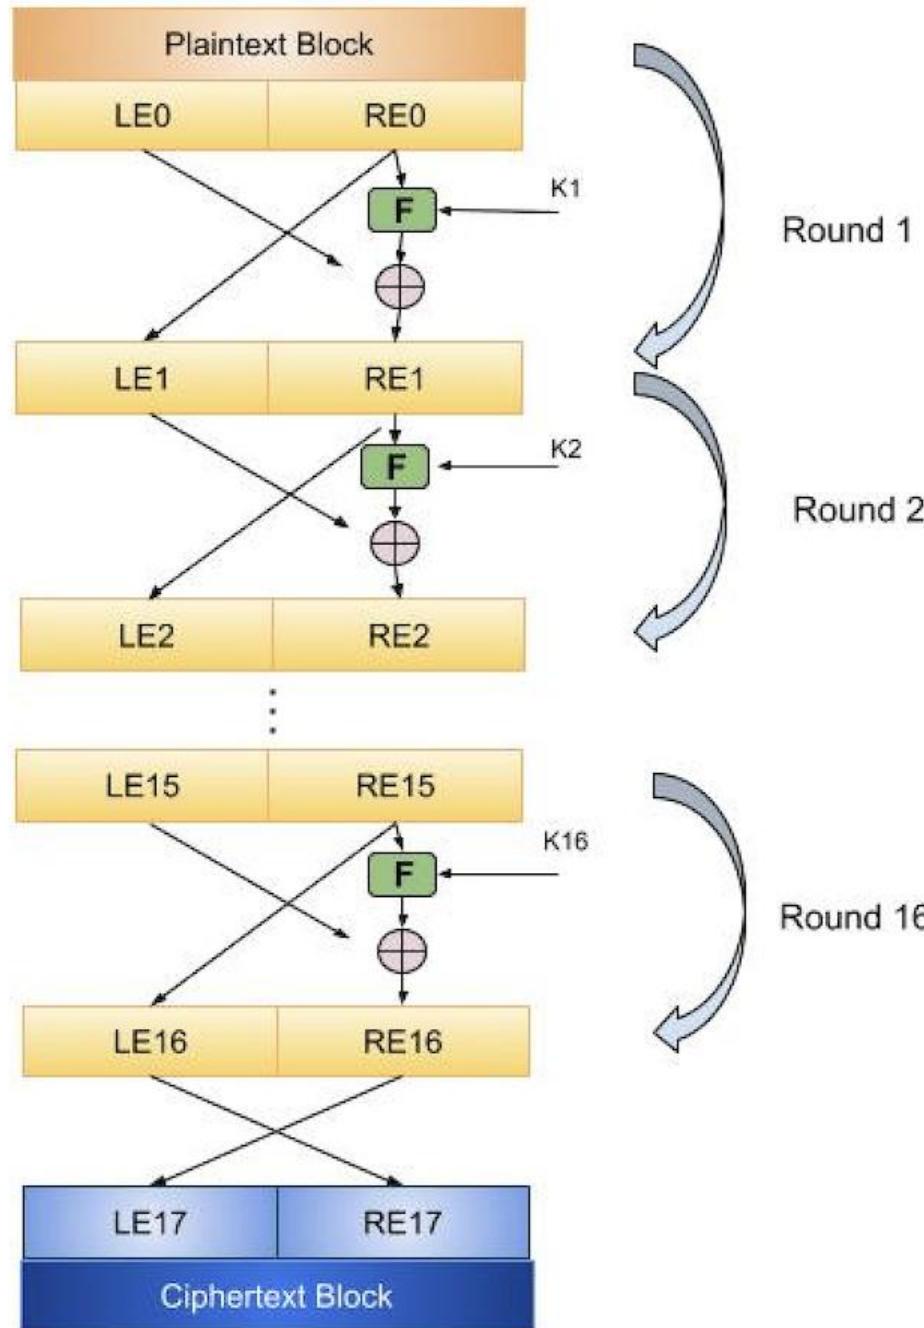

Feistel Cipher Structure

- ◆ Horst Feistel devised the **feistel cipher**
 - based on concept of invertible product cipher
- ◆ partitions input block into two halves
 - process through multiple rounds which
 - perform a substitution on left data half
 - based on round function of right half & subkey
 - then have permutation swapping halves
- ◆ implements Shannon's substitution-permutation network concept

Feistel Cipher Structure (1/3)

Feistel Cipher Structure (2/3)

Feistel Cipher Design Principles

◆ **block size**

- increasing size improves security, but slows cipher

◆ **key size**

- increasing size improves security, makes exhaustive key searching harder, but may slow cipher

◆ **number of rounds**

- increasing number improves security, but slows cipher

◆ **subkey generation**

- greater complexity can make analysis harder, but slows cipher

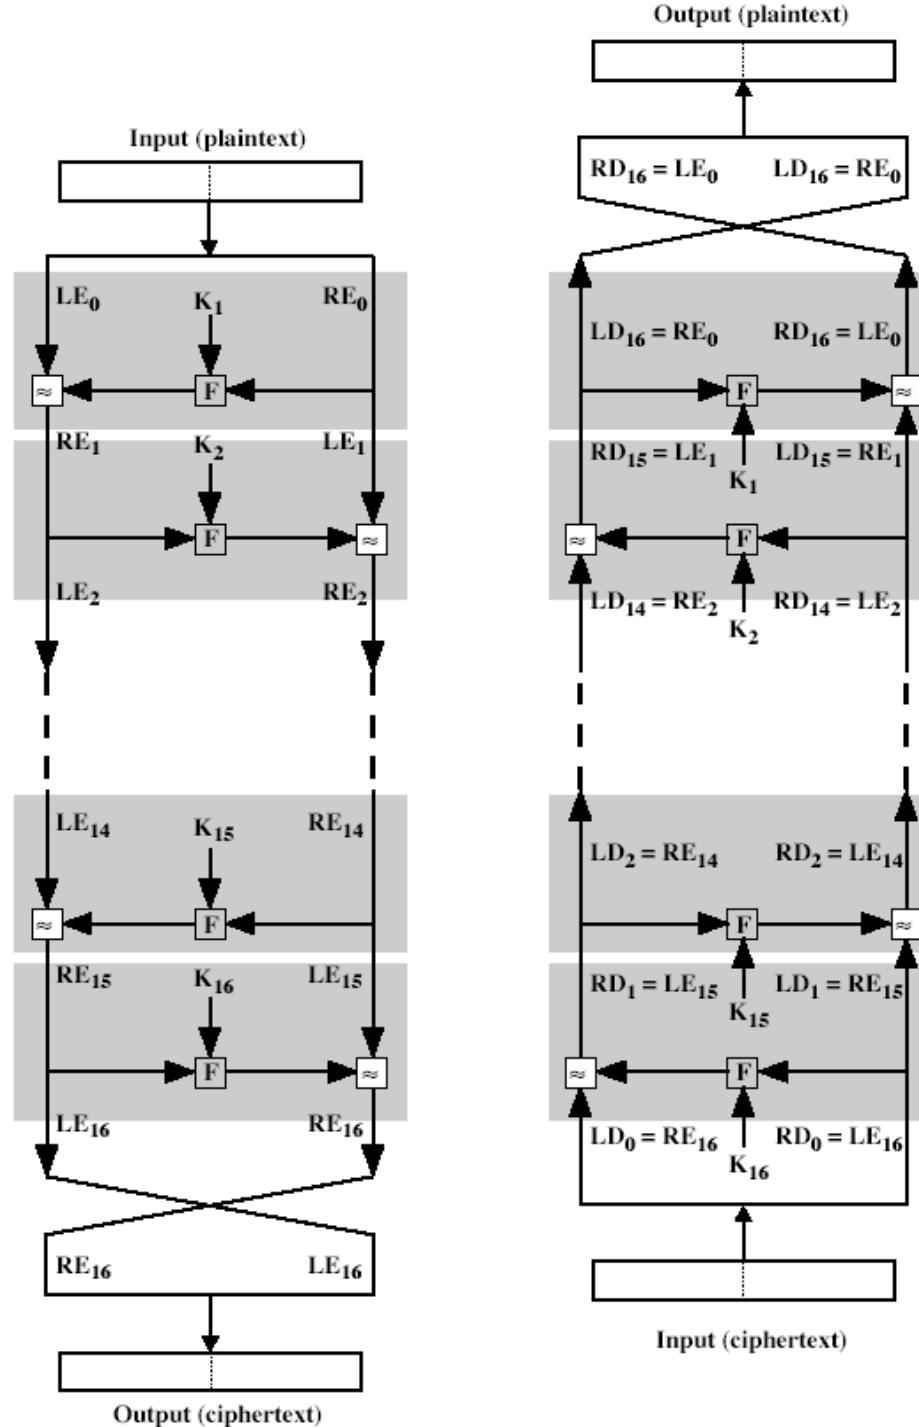

◆ **round function**

- greater complexity can make analysis harder, but slows cipher

◆ **fast software en/decryption & ease of analysis**

- are more recent concerns for practical use and testing

Feistel Cipher Encryption & Decryption

Data Encryption Standard (DES)

- ◆ most widely used block cipher in world
- ◆ adopted in 1977 by NBS (now NIST)
 - as FIPS PUB 46
- ◆ encrypts 64-bit data using 56-bit key
- ◆ has widespread use
- ◆ has been considerable controversy over its security

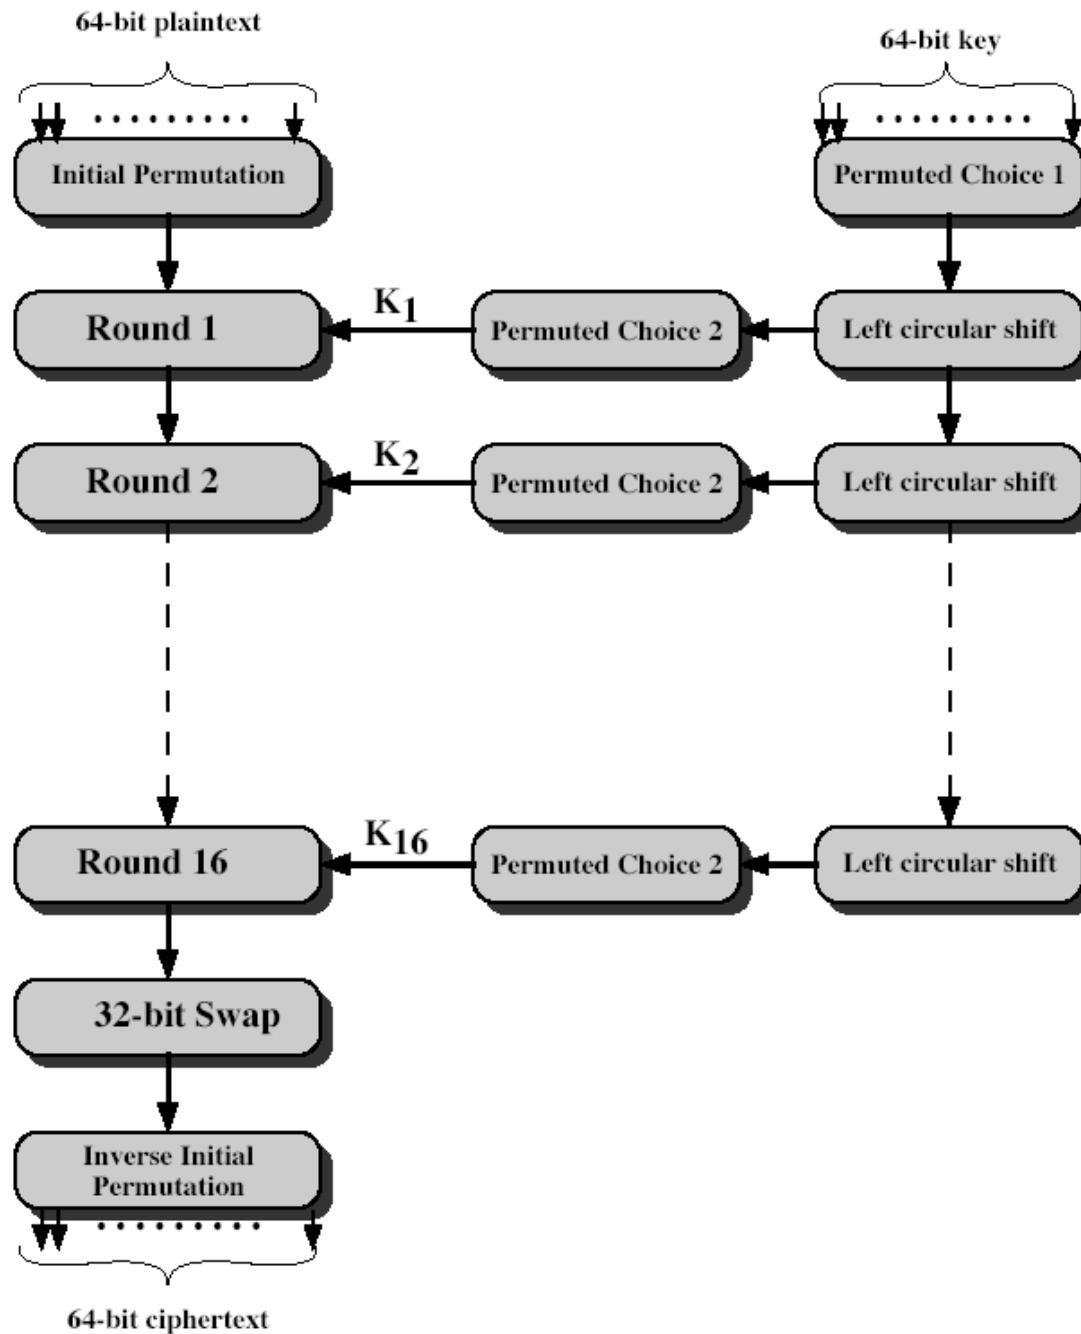

DES History

- ◆ IBM developed Lucifer cipher
 - by team led by Feistel
 - used 64-bit data blocks with 128-bit key
- ◆ then redeveloped as a commercial cipher with input from NSA and others
- ◆ in 1973 NBS issued request for proposals for a national cipher standard
- ◆ IBM submitted their revised Lucifer which was eventually accepted as the DES

DES Design Controversy

- ◆ although DES standard is public
- ◆ was considerable controversy over design
 - in choice of 56-bit key (vs Lucifer 128-bit)
 - and because design criteria were classified
- ◆ subsequent events and public analysis show in fact design was appropriate
- ◆ DES has become widely used, esp in financial applications

DES Encryption

Initial Permutation IP

- ◆ first step of the data computation
- ◆ IP reorders the input data bits
- ◆ even bits to LH half, odd bits to RH half
- ◆ quite regular in structure (easy in h/w)
- ◆ see text Table 3.2
- ◆ example:

IP (675a6967 5e5a6b5a) = (fffb2194d 004df6fb)

DES Round Structure

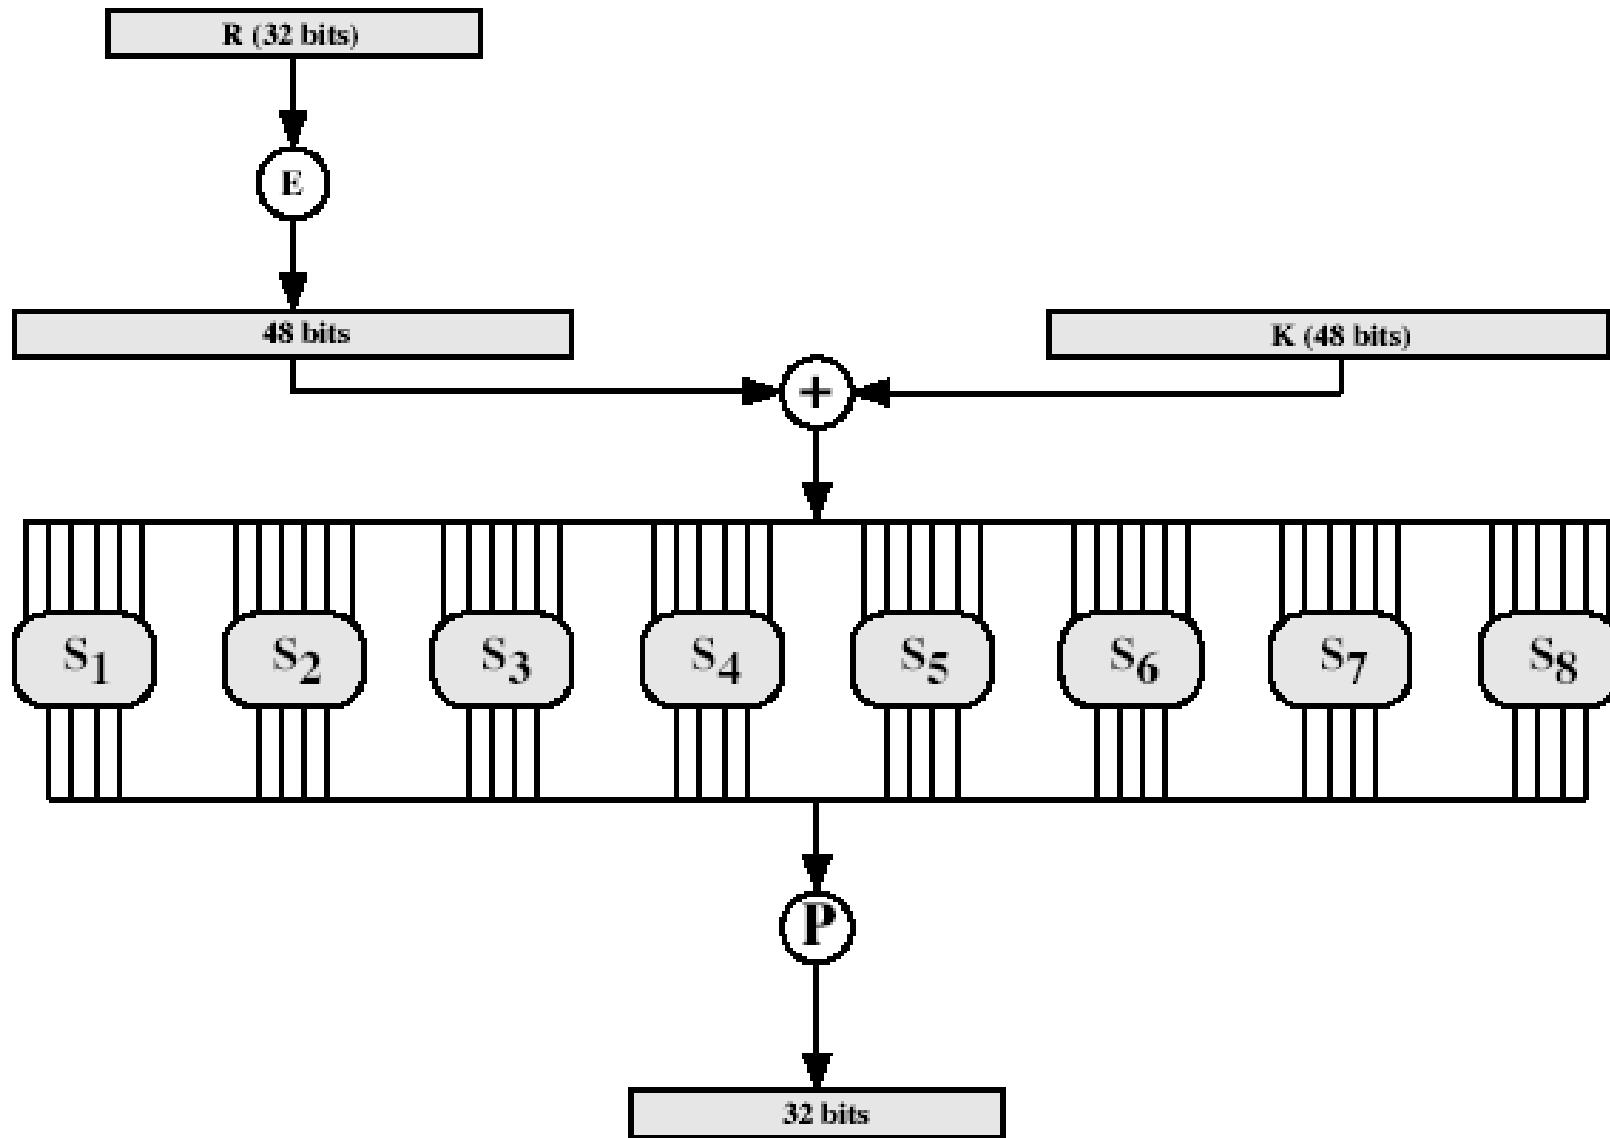

- ◆ uses two 32-bit L & R halves
- ◆ as for any Feistel cipher can describe as:

$$L_i = R_{i-1}$$

$$R_i = L_{i-1} \text{ xor } F(R_{i-1}, K_i)$$

- ◆ takes 32-bit R half and 48-bit subkey and:
 - expands R to 48-bits using perm E
 - adds to subkey
 - passes through 8 S-boxes to get 32-bit result
 - finally permutes this using 32-bit perm P

DES Round Structure

Substitution Boxes S

- ◆ have eight S-boxes which map 6 to 4 bits
- ◆ each S-box is actually 4 little 4 bit boxes
 - outer bits 1 & 6 (**row** bits) select one rows
 - inner bits 2-5 (**col** bits) are substituted
 - result is 8 lots of 4 bits, or 32 bits
- ◆ row selection depends on both data & key
 - feature known as autoclaving (autokeying)
- ◆ example:

S (18 09 12 3d 11 17 38 39) = 5fd25e03

DES Key Schedule

- ◆ forms subkeys used in each round
- ◆ consists of:
 - initial permutation of the key (PC1) which selects 56-bits in two 28-bit halves
 - 16 stages consisting of:
 - selecting 24-bits from each half
 - permuting them by PC2 for use in function f,
 - rotating **each half** separately either 1 or 2 places depending on the **key rotation schedule K**

DES Decryption

- ◆ decrypt must unwind steps of data computation
- ◆ with Feistel design, do encryption steps again
- ◆ using subkeys in reverse order (SK16 ... SK1)
- ◆ note that IP undoes final FP step of encryption
- ◆ 1st round with SK16 undoes 16th encrypt round
- ◆
- ◆ 16th round with SK1 undoes 1st encrypt round
- ◆ then final FP undoes initial encryption IP
- ◆ thus recovering original data value

Avalanche Effect

- ◆ key desirable property of encryption alg
- ◆ where a change of **one** input or key bit results in changing approx **half** output bits
- ◆ making attempts to “home-in” by guessing keys impossible
- ◆ DES exhibits strong avalanche

Strength of DES – Key Size

- ◆ 56-bit keys have $2^{56} = 7.2 \times 10^{16}$ values
- ◆ brute force search looks hard
- ◆ recent advances have shown is possible
 - in 1997 on Internet in a few months
 - in 1998 on dedicated h/w (EFF) in a few days
 - in 1999 above combined in 22hrs!
- ◆ still must be able to recognize plaintext
- ◆ now considering alternatives to DES

Block Cipher Design Principles

- ◆ basic principles still like Feistel in 1970's
- ◆ number of rounds
 - more is better, exhaustive search best attack
- ◆ function f:
 - provides "confusion", is nonlinear, avalanche
- ◆ key schedule
 - complex subkey creation, key avalanche

Summary

- ◆ have considered:
- ◆ block cipher design principles
- ◆ DES
 - details
 - strength

Thank you – Q&A
